Network Directories and their Structure

Lightweight Directory Access Protocol (LDAP)

Nick Urbanik <nicku@nicku.org>

A computing department

Network Directories and their Structure

Lightweight Directory Access Protocol (LDAP)

Organising accounts in a large network

Reference book: *Understanding and Deploying LDAP Directory Services*, Second Edition, Timothy Howes, Mark Smith and Gordon Good, Macmillan, 2003.

Our library: TK 5105.595 .H69 2003

(also see references at the end of slides)

Account Information

- The computer uses numbers to refer to users and groups
- Humans prefer to use names (like nicku)
- When you create files in your shared network drive, the client must access them using the same numbers
- The user ID numbers and group ID numbers must be the same on all computers
- Otherwise won't be able to read own files!

Network Accounts

- ```
  $ ls -ln file
  -rw-rw----    1 500      500          2057 Nov  1  2000 file
  ```
- Now nicku with user ID number 500 and group ID 500 can read and write this file
- . . . But nicku with user ID number 2270 and group ID number 2270 cannot access the file at all:

  ```
  $ id
  uid=2270(nicku) gid=2270(nicku) groups=2270(nicku),14171(staff)
  ```

Network Accounts — 2

- The user ID numbers and group ID numbers on files on a network drive are fixed
- The user ID numbers should remain unchanged for all users who read/write the network drive.
  ```

Methods of achieving this

- Have a *directory server* of some kind
- The directory server associates a fixed user ID number with each login ID
- . . . and a fixed group ID number for each group ID
- On NT, these are called SIDs (security IDs)

Directory systems for authentication

- Proprietary:
  - Novell Directory Services (NDS)
  - Microsoft Active Directory (M? AD)
  - NT 4 domain
  - NIS + (Network Information System plus)
  - NIS
- Open protocols:
  - LDAP
  - Hessiod

Proprietary application directories

- Application-specific directories:
  - Lotus Notes
  - cc:Mail
  - Microsoft Exchange
  - Novell GroupWise
- These directories come bundled with, or, embedded into an application such as email.
- If add another such application, must manage one more directory ("$N + 1$ directory problem")
- If add another user, must add to all the directories.

Problem with proprietary directories

- Need put the same user into many different directories
- Need maintain N times the number of user accounts, where N is the number of directories.
- This is just too much work.
- The accounts get out of sync.

Why not buy Microsoft AD?

- Microsoft leverage their monopoly on the desktop to "embrace and extend" free software written by others
- Example:
  - Kerberos is a "Network Authentication Service", an IETF standard (see RFC 1510)
  - Kerberos is written by cooperating programmers round the world
  - Microsoft took Kerberos, and modified the protocol very slightly (they classified this change as a "trade secret")
  - So that MS destops can use MS Kerberos servers, but not non-MS Kerberos servers.
- Although MS claims to support standards, MS solutions are highly proprietary
- Designed to lock the user into an all-MS solution.
- Could be an expensive and insecure mistake.

ldap— Why?

- Non-proprietary, IETF standard
  - No vendor lock-in
  - Use standard software components
- Supports authorisation as well as authentication
  - E.g., access if "staff, or year 3, group W, CSA student"
- Very general purpose: use for email, system authentication, application authentication, . . .
- Reasonably secure
- Robust
- Extensible
- Good open source implementation available at http://www.OpenLDAP.org/

ldap Terminology

- LDAP model is *hierarchical*, i.e., tree-structured
- Each object in a directory is an *entry*
- Each individual item in an entry is an *attribute*
- Each entry has a unique full name called its *distinguished name* or *dn*
- Each entry has a short name that is unique under its parent, called its *relative distinguished name*, or *rdn*.
- The organisation of names in the directory is called the *namespace*
- An important initial task is *namespace design*

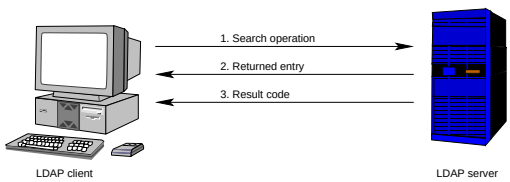
What is ldap?

- The LDAP *protocol*, a standard Internet protocol
- Four *models*:
  - *information model*—what you can put in directory
  - *naming model*—how name directory data
  - *functional model*—what you can do with data
  - *security model*—no unauthorised access
- LDAP Data Interchange Format (LDIF), a standard text format for representing directory data
- LDAP *server software*
- *command line utilities* (`ldapsearch`, `ldapmodify`, . . .)
- LDAP API

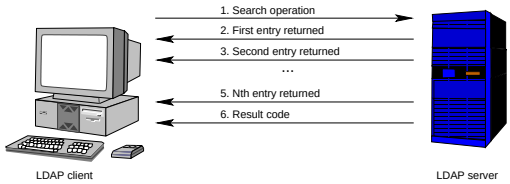
The ldap Protocol

- LDAP is a *message-based* protocol
  - client sends one or more requests to server, one message per request
    - Each message has its own *message ID*
  - server replies with one or more replies. Each reply has message ID matching that of request.
  - Can send several messages at once; results can be out of order, no problem

Simple Search Examples

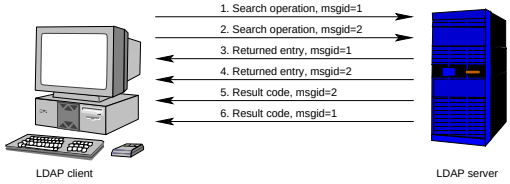


- Here a client gets one single entry from the directory



- A client gets multiple responses from the directory

Multiple Simultaneous Requests



- A client sends multiple requests to the directory
- Note that each request has its own `msgid`
- Responses may come out of order (see last two result codes); that's okay.
  - These details are hidden from programmer by the SDK (software development kit)

ldap Protocol Operations

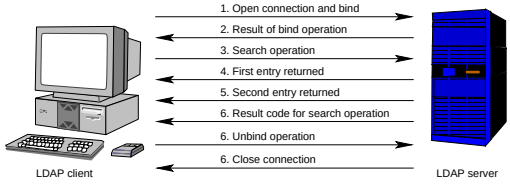
- Interrogation operations: `search`, `compare`
- Update operations: `add`, `delete`, `modify`, `modify DN` (rename)
- Authentication and control operations: `bind`, `unbind`, `abandon`

`bind` operation allows a client to identify itself sending identity and authentication credentials

`unbind` operation allows client to terminate session

`abandon` operation allows a client to tell the server it does not need the results of an operation it had requested earlier

Typical ldap Exchange



- The *bind operation* provides a *distinguished name* (DN) and other credentials to authenticate against the directory
- The *unbind operation* is a request to disconnect

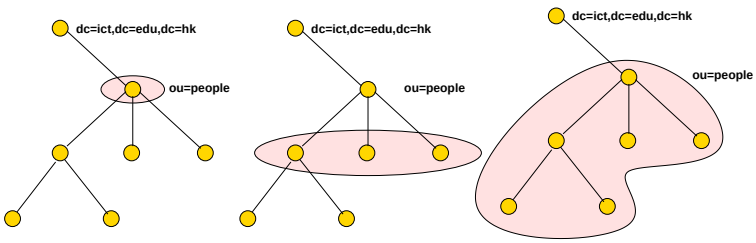
ldap Encoding: ber

- The LDAP protocol uses the *Basic Encoding Rules*, BER to encode various data types in a platform independent way
- These are the same rules as used in SNMP
- Therefore it is not a simple text-based protocol, like HTTP or SMTP.

ldap Search Operation

- Used to search for entries and retrieve them
  - This is the only way to read the directory
- Takes eight parameters, including:
  - DN of base object for search — see slide §13
  - search scope — see slide §13
  - search filter — see slide §27
  - list of attributes to return

Search Scope



Search scope = *base*

Search scope = *one*

Search scope = *subtree*

- In each case, the search base is `ou=People,dc=ict,dc=edu,dc=hk`

The Compare Operation

- Not very useful
- I use it for determining if a user belongs to a particular group
- main difference from search:
  - If compare on an attribute that does not exist in a particular entry, returns code indicating this
  - If search for an attribute that does not exist in a particular entry, then get nothing returned.

Add Operation

- Creates a new entry, given two parameters:
  - DN of new entry
  - list of attributes and their values to put in the new entry
- Will succeed if and only if:
  - parent of new entry exists
  - no entry of same name exists
  - new entry matches requirements of schemas
  - access control allows operation

Delete Operation

- Deletes an entry
- Takes DN of entry to delete
- Succeeds if:
  - entry exists
  - entry has no children
  - access control allows operation

Modify dn (Rename) Operation

- Used to rename or move an entry from one place in tree to another
- Has four parameters:
  - Old DN
  - New DN
  - New RDN for entry
  - optional flag indicating whether to delete the old RDN attribute from the entry
- Succeeds if:
  - entry exists
  - new name not already used
  - access control allows operation

Modify Operation

- Allows updating existing entry
- Can add, delete or replace attributes
- Can modify many attributes in one modify operation
- Succeeds if and only if:
  - entry exists
  - all attribute modifications must succeed
  - resulting entry obeys schemas
  - access control permits modification

Bind Operation

- authenticates client to the directory
- Three bind types:
  - *simple bind*, where send DN and password in clear text to server
    - Need to use TLS to encrypt communication in this case
  - SASL bind
    - SASL = Simple Authentication and Security Layer
    - A standard protocol independent way of negotiating and performing authentication
  - *anonymous bind*, where send DN but no passwords
- Client can bind, perform operations, bind again, and perform other operations

Command Line Utilities

- With OpenLDAP, the main utilities (in RH Linux, in the package `openldap-clients`) are:

  `ldapsearch` Query directory

  `ldapmodify` Perform the modify operation on an entry — see §19

  `ldapdelete` Delete an entry

  `ldapadd` Add an entry

  `ldapmodrdn` Rename an entry

  `ldapcompare` Compare operation

  `ldappasswd` Change LDAP password using LDAPv3 Password Modify (RFC 3062) extended operation

- Each one has a detailed `man` page

Common Parameters

- All commands use the SASL (Simple Authentication and Security Layer) protocol by default
  - But won't work here:
  - . . . we use simple authentication here (we send plain text passwords over link encrypted with Transport Layer Security i.e., TLS or SSL)
- "`-x`" use simple authentication instead of SASL
- specify hostname of server with `-h`, e.g., `-h ldap.vtc.edu.hk`
- Specify a DN to bind with using `-D` (see §19)
- Specify a password on command line with `-w` ⟨*password*⟩ or interactively prompt using `-W`
  - See §19, §31 for examples

`ldapsearch`

- Specify *base* of search with `-b`
  - Default can be specified as a line in `/etc/openldap/ldap.conf`, e.g.,

    ```
    BASE dc=tyict,dc=vtc,dc=edu,dc=hk
    HOST ldap.tyict.vtc.edu.hk
    ```

- Specify *scope* of search with `-s [base|one|sub]`
  - Default scope is subtree scope
- See §30 for more examples.

ldap Data Interchange Format ldif

- A standard defined in RFC 2849
- Used to import, export directory data in a standard way
  - A bit like how all spreadsheets understand tab-delimited text files
- Can also specify update operations to directory entries.

Example ldif

```
dn: uid=nicku,ou=People,dc=ict,dc=vtc,dc=edu,dc=hk
uid: nicku
cn: Nick Urbanik
givenName: Nick
sn: Urbanik
mail: nicku@nicku.org
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: posixAccount
objectClass: top
loginShell: /bin/sh
uidNumber: 1000
gidNumber: 1000
homeDirectory: /opt/nicku
mail: nicku@nickpc.tyict.vtc.edu.hk
description: Interested in free software
```

Update Operation in ldif

```
$ cat /tmp/update-nick.ldif
dn: uid=nicku,ou=People,dc=ict,dc=vtc,dc=edu,dc=hk
changetype: modify
replace: mail
mail: nicku@nicku.org
-
add: title
title: Lecturer in SNM
-
add: jpegPhoto
jpegPhoto:< file://tmp/penguin.jpg
-
delete: description
-
$ ldapmodify -x -D 'uid=nicku,ou=People,dc=ict,dc=vtc,dc=edu,dc=hk \
-W -f /tmp/update-nick.ldif
Enter LDAP password:
modifying entry "uid=nicku,ou=People,dc=ict,dc=vtc,dc=edu,dc=hk"
```

ldap Schemas

- The directory has a set of rules that determine the allowed object-classes and attributes
- Called the *schemas*
- Can be defined in
  - ASN.1, or
  - University of Michigan style, or
  - LDAPv3 style
- Each object, and its syntax, are both defined using OIDs, as in SNMP.

Attributes — Defined in Schema

- For each attribute, schema defines:
  - Name
  - Description
  - Permitted compare operations
  - Syntax (i.e., data type).
- LDAP server ensures that all added data matches the schema

ldap objectClass — 1

- Each attribute belongs to one or more **objectClass**es
- objectClasses are defined in schemas
- Defines what attributes *must*, or *may* be present in an entry
- objectClass definition includes:
  - Name of objectClass
  - What subclass this is derived from
  - The type of objectClass: *structural*, *auxiliary* or *abstract*
  - Description
  - List of *required* attributes
  - List of *allowed* attributes

Object Class and Attributes

- The entry can use all the attributes allowed in all the objectClasses.
  - See in slide §24 how LDAP attributes differ from attributes in, say, a Java class

ldap Object Class Inheritance

- LDAP implements a limited form of object oriented inheritance
- One entry may contain many objectClasses
  - We say, "an entry belongs to many classes"
- Cannot override any schema rules defined in superior class
- Example: top ◁– person ◁– organizationalPerson ◁– inetOrgPerson
  - In `/etc/openldap/schema`, `core.schema` defines person, organizationalPerson; `inetorgperson.schema` defines inetOrgPerson
- A class derived from another class includes the attributes of its superior class(es)

ldap Object Class Type

- objectClass has a type: *structural*, *auxiliary*, or *abstract*
- Default is *structural*
- **Structural** is for the fundamental, basic aspects of the object, e.g., **person**, **posixGroup**, **device**.
- **Auxiliary** classes place no restrictions on where an entry is stored, and are used to add more attributes to structural classes.
- **Abstract** classes are not usually created by users; the class **top** and **alias** are abstract.

Structural Classes

- Rule of LDAP standards: if an entry belongs to more than one *structural* class, they must be related by inheritance
  - OpenLDAP 2.0.x does not implement this restriction, but OpenLDAP 2.1.x and later versions (including 2.2.x) do.
- To get around this, can either:
  - Implement a new objectClass that is of type auxiliary that allows the attributes you require—see http://www.openldap.org/faq/data/cache/883.html
  - Implement a new objectClass that inherits from both unrelated structural classes and use that—See http://www.openldap.org/faq/data/cache/807.html .

Entries: Selecting Object Class Types

- Entries contain one or more *objectClass*es
- Choose the attributes you need
- Select the objectClasses that provide these attributes
- Add the objectClass to your entry.

Rules for ldap Entries

- Each entry must be a member of the objectClass `top`
- Each entry must be a member of the objectClass that provides the attributes
- Exactly one objectClass should be structural, the rest auxiliary (or abstract)
  - An entry may belong to more than one structural class if all structural classes are related by inheritance

Namespace of attributes

- There is only one namespace for attributes
- The definition of the attribute **`cn`** (common name) is the same for all objectClasses that support the **`cn`** attribute.

Example objectTypes

- Here is the definition for person from core.schema:

```
objectclass ( 2.5.6.6 NAME 'person'
  SUP top STRUCTURAL
  MUST ( sn $ cn )
  MAY ( userPassword $ telephoneNumber $
        seeAlso $ description ) )
```

- This says a person entry *must* contain:
  - a surname (`sn`) and
  - common name (`cn`),
- and *may* contain a userPassword, a telephoneNumber, a description, and a reference to another LDAP entry.

Want to support network login

- Does the objectClass person provide what is needed for network login?
- For network accounts, need replace (at minimum):
  - `/etc/passwd`
  - `/etc/group`
  - `/etc/shadow`
- So in addition to attributes of person, need:
  - User ID name (log in name)
  - User ID number
  - Primary group ID number
  - Gecos information (fifth field of `/etc/passwd`)
  - Home directory
  - Login shell
- Also the password aging information from `/etc/shadow`

Supporting network login

- Use the existing objectClass `posixAccount`:

```
objectclass ( 1.3.6.1.1.1.2.0 NAME 'posixAccount'
  SUP top AUXILIARY
  DESC 'Abstraction of an account with POSIX
        attributes'
  MUST ( cn $ uid $ uidNumber $ gidNumber $
         homeDirectory )
  MAY ( userPassword $ loginShell $ gecos $
        description ) )
```

- Provides fields from `/etc/passwd`

Authorisation as well as authentication

- Suppose you have an online web-based quiz, want only staff, or year 3, group W, CSA student to be allowed to log in.
- For this to work:
- Each person entry has attributes including:
  - `Course`, e.g., 41300
  - `classCode`, e.g., W
  - `Year`, e.g., 3
  - `acType`, e.g., STU or STF

ldap filters

- LDAP provides a standard method for selecting authenticated users who match authorisation criteria
- The filter to select staff or students in year 3, CSA, group W is:

```
(|(acType=STF)(&(year=3)(course=41300)
(classcode=W)))
```

(This line is wrapped to fit on the slide, but normally given on one line)

- All filters are enclosed in parentheses
- Filters can be combined with OR '|', AND '&'

RFC 2254 — 1

Find this in `/usr/share/doc/openldap-2.0.27/rfc/rfc2254.txt`

```
filter     = "(" filtercomp ")"
filtercomp = and / or / not / item
and        = "&" filterlist
or         = "|" filterlist
not        = "!" filter
filterlist = 1*filter
item       = simple / present / substring
simple     = attr filtertype value
filtertype = equal / approx / greater / less
equal      = "="
approx     = "~="
greater    = ">="
less       = "<="
```

RFC 2254 — 2

```
present    = attr "=*"
substring  = attr "=" [initial] any [final]
initial    = value
any        = "*" *(value "*")
final      = value
attr       = AttributeDescription from Section 4.1.5 of [1]
value      = AttributeValue from Section 4.1.6 of [1]
[1] is RFC 2251.
Grammar is defined in RFC 822
```

Examples of Filters from RFC 2254

Return all entries in the scope of the search with attribute `cn` having the value "Babs Jensen":

```
(cn=Babs Jensen)
```

Return all entries in the scope of the search which do **not** have the attribute `cn` with the value "Tim Howes":

```
(!(cn=Tim Howes))
```

Return all entries in the scope of the search which have the attibute

```
(&(objectClass=Person)(|(sn=Jensen)(cn=Babs J*)))
```

```
(o=univ*of*mich*)
```

More Filter Examples

- Note that a filter such as `(age>21)` is not allowed.
- Use `(!(age<=21))` instead.
- Similarly, instead of `(age<21)`, use `(!(age>=21))`.
- search for all students in group X, year 3, CSA course, who enrolled this year:

  ```
  (&(year=3)(course=41300)(classcode=W)
  (registrationDate=*-03))
  ```

  Note that there is a substring match on `registrationDate` here. A substring match is like a wildcard in filename matching.

Escaping Characters in a Filter

Character	Escape Sequence
* (asterisk)	\2A
((left parenthesis)	\28
) (right parenthesis)	\29
\ (backslash)	\5C
NUL (the null byte)	\00

Using the command line tool ldapsearch

- `$ ldapsearch -x -h ldap.vtc.edu.hk \`
  `-b "dc=vtc.edu.hk" \`
  `"(&(department=ICT)(site=TY)`
  `(|(acType=STF)`
  `(&(year=3)(course=41300)(classcode=W))))" cn`
- The result is a list of all the DNs that match the filter, with the students' and staff names.
- Can filter out the DNs and blank lines by piping the command though `grep '^cn:' | sort`

Output of this `ldapseach` without staff

```
cn: CHAN Kwok Kam

```

`ldapsearch`

- Needs the `-x` option to work here
- Check ssl works with the `-ZZ` option
- Can "bind" as a user to get all the info you are allowed to see after binding:

```
$ ldapsearch -x -W -D \
"uid=nicku,ou=People,dc=tyict,dc=vtc,dc=edu,dc=hk" \
'(uid=nicku)'
```

- Can then see own passwords

ldap URLs: RFC 2255

- Have the form:
- `ldap://`⟨*host*⟩`:`⟨*port*⟩`/`⟨*base*⟩`?`⟨*attr*⟩`?`⟨*scope*⟩`?`⟨*filter*⟩

```
ldapurl    = ldap://" [hostport] ["/"
                  [dn ["?" [attributes] ["?" [scope]
                  ["?" [filter] ["?" extensions]]]]]
```

- The ⟨*base*⟩ or **dn** is the distinguished name of the starting entry for your search.
- ⟨*scope*⟩ is one of **base**, **one** or **sub**
- Examples:

```
ldap://ictlab/ou=People,dc=tyict,dc=vtc,dc=edu,dc=hk?uid?one?(uid=nicku)
```

mod_auth_ldap with Apache

- **mod_auth_ldap** is part of the **httpd** RPM package on Fedora Core 1.
- Here we allow staff or students from group W, year 3 CSA to access the web pages under http://hostname/group-w/ if the user provides a correct password:

```
<Location "/group-w">
     AuthType Basic
     AuthName ``\LDAP authentication to class W only"
     AuthLDAPURL ldap://ldap.tyict.vtc.edu.hk/
ou=People,dc=tyict,dc=vtc,
dc=edu,dc=hk?uid?one?(|(acType=STF)(\&(course=41300)
(classCode=W)(year=3)))
     require valid-user
</Location>
```

- See http://httpd.apache.org/docs-2.0/mod/mod_auth_ldap.html, and also http://httpd.apache.org/docs-2.0/mod/mod_ldap.html for manual.

Authorisation of Students and Staff

- We need a new schema to support the required attributes
- We create three new objectClasses and associated attributes:
- The first is common to students and staff:

```
objectclass ( 1.3.6.1.4.1.11400.2.2.1 NAME 'institute'
  SUP top AUXILIARY
  DESC 'Any person in the institute, staff or student'
  MAY ( acOwner $ acType $ answer1 $ answer2 $
        answer3 $ batchUpdateFlag $ department $
        site $ instituteEmail ) )
```

Other objectTypes for IVE

- Then on top of this, we have attributes for students:

```
objectclass ( 1.3.6.1.4.1.11400.2.2.2 NAME 'student'
        SUP top AUXILIARY
        DESC 'A student in the institute'
  MAY ( academicYear $ award $ classCode $ course $
        courseDuration $ FinalYear $
        registrationDate $year $
        fullPartTime ) )
```

- . . . and staff:

```
objectclass ( 1.3.6.1.4.1.11400.2.2.3 NAME 'staff'
        SUP top AUXILIARY
        DESC 'A staff member of the insitute.'
  MAY ( titleDes $ employerID ) )
```

The whole schema for IVE

- The whole schema can be seen here: http://nicku.org/oids/institute.schema

Case Study: ICT laboratories

- Old system:
- An ancient DEC Alpha running NIS
- Hardware insufficient for demand
- *Very* expensive maintenance, stopped paying
- Technician reported a hardware failure close to first day of term
- New system:
- We were planning to introduce LDAP authentication gradually
- Failure required planning move faster
- Needed to maintain old legacy accounts, plus introduce new accounts

ICT case study

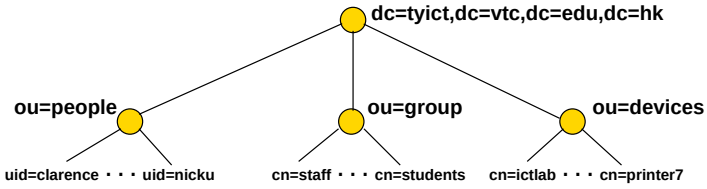
- We chose OpenLDAP on Linux
- Running on an Acer Altos dual CPU P-III
- Migrated from the NIS using the migration scripts provided with OpenLDAP
- Migrated from the VTC LDAP accounts using a Perl program, written (quickly!) for the purpose,
- Uses the `Net::LDAP` Perl modules

ICT case study — 2

- After migrating the legacy accounts, and creating new accounts for staff, full and part time students, had more than 5000 accounts
- The LDAP server was using a high CPU load
- Was able to solve this using caching:
- Use `nscd` (name service caching daemon) on client
- Use memory in server to increase local cache size drastically.
- CPU load reduced to a very acceptable level.

Directory Structure — 1

- The ICT LDAP server namespace design:

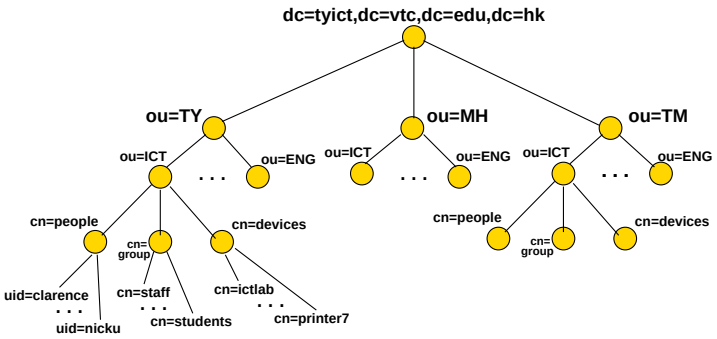


Directory Structure — 2

- We chose a fairly flat directory structure
- Recommended by reference, pages 239, 249.
- Reason: flexibility:
- allows for change without major reorganisation of data.

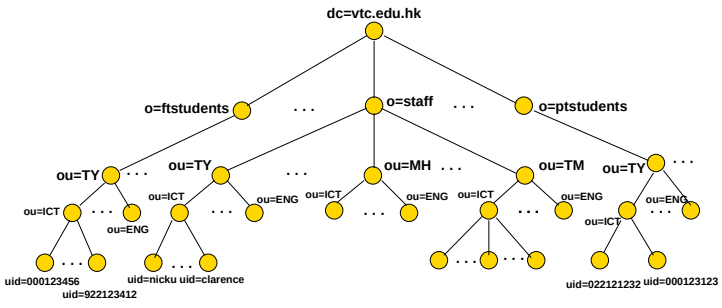
Hierarchical Directory Structure

- This directory structure is hierarchical:



New VTC ldap Namespace

- This new VTC LDAP namespace was introduced in April 2003:



Hierarchical Directory Structure

- This is an alternative data arrangement
- Divide into different campuses
- Advantage: can easily delegate management to local campus
- But: suppose ENG changes to EE?
- Suppose staff move from one department to another?
- Suppose equipment is transferred?
- Not only need change the attributes in the entry, but also move the entry.
- Overall, a flatter structure is easier to manage.

Directory Design Guidelines

- Design as flat as possible given constraints:
- Replication
- Access Control
- Limitations of directory software
- Requirements of applications that use the directory

Designing a Schema

- After selecting the schema attributes needed for your application, you may find that not all are available with the server
- Search web for more schemas
- If none provide all you need,
- Select a suitable structural base class
- Create an auxiliary class to be used with the base class
- Define the objectClass and its attributes

Designing a Schema: Example

- For our ICT LDAP server, we use enough attributes to be able to log in
- But we also want to select users on the basis of course, year, class
- Want to add these attributes to the existing objectClasses
- Create three object classes:
- Institute
- Student
- Staff
