Programming LDAP with Perl

Net::LDAP

Nick Urbanik <nicku@nicku.org>

A computing department

What is Net::LDAP?

- Mature and fully-featured Perl library
- Pure Perl; very easy to install on any platform
  - On Windows, do

```
D:\>ppm
PPM - Programmer's Package Manager version 3.1.
Copyright (c) 2001 ActiveState SRL. All Rights Reserved.
...

ppm> install perl-ldap
```

  - On other platforms, do:

```
$ sudo perl -MCPAN -e 'install Net::LDAP'
```

- Excellent documentation
  - Start with

```
$ perldoc Net::LDAP
```

- Helpful mailing list

Contents

Authentication

- The *bind* operation
- Three types: *anonymous*, *simple*, *SASL*
- Anonymous:
```
my $result = $ldap->bind;
```
- Simple:
```
my $result =
   $ldap->bind( $dn, password => $password );
```
  - Danger! Password sent in clear text unless use TLS (see slide §18)

Connecting

- Connect when construct the Net::LDAP object:
```
my $ldap = Net::LDAP->new( $hostname )
  or die "Unable to connect to $hostname: $!";
```
- See `perldoc Net::LDAP` for many other parameters you can pass in constructor

Return Values

- Most Net::LDAP methods return an object
  - returned object provides method to obtain results of operation
- result code returned by `$result->code`
- error message returned by `$result->error`
- Example:
```
warn $result->error if $result->code;
```

Searching

- Need three things for a search:
  - *search base*, *scope* and *filter*

```
my $result = $ldap->search(
   base => 'dc=tyict,dc=vtc,dc=edu,dc=hk',
   scope => 'sub',
   filter => '(uid=nicku)'
);
die $result->error if $result->code;
```

- The result also contains the matching entries:

```
foreach my $entry ( $result->entries ) {
    $entry->dump;
}
```

  - Methods of the object that results from a search documented in `perldoc Net::LDAP::Search`

Entry Object

- Entry object is used:
  - to create new entries and
  - is available from a search
- Documented in `perldoc Net::LDAP::Entry`
- Methods:

  `dn` returns the DN for the entry:

```
my $dn = $entry->dn;
```

  `exists` tests if an attribute exists in the entry:

```
do_something() if $entry->exists( 'cn' );
```

Entry Object — 2

- Methods:

  `get_value` obtain the value(s) for an attribute in the entry

```
my $value = $entry->get_value( 'cn' );
```

  Multivalued attributes: Some attributes have more than one value. For these, `get_value` returns the first value in a scalar context, and all of them in a list context:

```
my $first  = $entry->get_value( 'objectClass' );
my @values = $entry->get_value( 'objectClass' );
```

  `attributes` returns a list of attributes the entry contains

```
my @attrs = $entry->attributes;
```

Displaying an Entry

- If all attributes can be printed, then this function could display an entry:

```
sub display_entry {
    my $entry = shift;
    my @attrs = $entry->attributes;

    foreach my $attr ( @attrs ) {
        my @value = $entry->get_value( $attr );

        foreach my $value ( @value ) {
            print "$attr: $value\n";
        }
    }
}
```

Controlling What's Returned

- By default, LDAP server returns attributes and their values for each entry.
- Can ask server for just the types; then value returned for each attribute is empty:

```
my $r = $ldap->search(
    base    => 'dc=tyict,dc=vtc,dc=edu,dc=hk',
    filter => '(cn=Nick*)',
    typesonly => 1,
);
```

- Access control limits what attributes are returned; can limit further by specifying a list of required attributes:

```
my $r = $ldap->search(
    base    => 'dc=tyict,dc=vtc,dc=edu,dc=hk',
    filter => '(cn=Nick*)',
    attrs   => [ qw(uid cn) ],
);
```

Adding Entries

- Pass an array reference of attribute and value pairs to the `add` method:

```
my $r = $ldap->add( $dn,
    attrs => [
        cn => 'HP5000-A204e',
        objectClass => [ qw/device ieee802Device/ ],
        description => 'Printer in A204e',
    ],
);
```

- . . . or, create an Entry object and call the `update` method:

```
my $dn = 'ou=devices,dc=tyict,dc=vtc,dc=edu,dc=hk';
my $entry = Net::LDAP::Entry->new;
$entry->dn( $dn );
$entry->add( cn => 'HP5000-A204e' );
$entry->add(
    objectClass => 'device',
    description => 'Printer in A204e',
);
$mesg = $entry->update( $ldap );
```

Adding New Entries

- Net::LDAP supports four ways of adding new entries to a directory:
  - the `add` method;
  - the Entry class;
  - LDIF: Same as adding with the Entry class, except Entry is read from a file via the LDIF module
  - DSML: Same as adding with the Entry class, except Entry is read from a file via the DSML module

Deleting an Entry

- Can delete an entry by passing a DN:

```
my $dn = 'ou=dev,dc=tyict,dc=vtc,dc=edu,dc=hk';
my $r = $ldap->delete( $dn );
```

- . . . or like many Net::LDAP methods, you can pass an entry where a DN is expected:

```
$entry = find_entry_to_delete();
$r = $ldap->delete( $entry );
```

Modifying an Entry

- `modify` operation has four sub-operations:

  `add`
  - add new attributes
  - add values to existing multivalued attributes

  `delete`
  - delete whole attributes
  - delete values from within existing attributes

  `replace` replace attributes or add if necessary

  `moddn` rename an entry under same or different parent

Modify — `add`

- Add a new attribute, or a new value to an existing multi-valued attribute:

```
$r = $ldap->modify( $dn,
    add => {
        mail => 'nicku@nicku.org'
    }
);
```

- An error is returned if:
  - the attribute exists and is not multi-valued;
  - the attribute exists and is multi-valued and the value already exists;
  - the schema does not allow the attribute.

Modify — `delete`

- To delete all instances of the attribute in the entry:

```
$r = $ldap->modify( $dn,
    delete => [ 'mail' ]
);
```

- You can delete specific values:

```
$r = $ldap->modify( $dn,
    delete => { 'mail' => [ 'nicku@abc.com' ] }
);
```

Modify — `replace`

- Replace whole attributes:

```
$r = $ldap->modify( $dn,
    replace => { 'mail' => 'nicku@xyz.com' }
);
```

- Multi-valued:

```
$r = $ldap->modify( $dn,
    replace => {
        'mail' => [ qw(nicku@xyz.com
                       nick@iohk.com) ]
    }
);
```

Using Start TLS

- LDAPv3 supports the *Start TLS* extension
- Allows a client to request that the server begin encrypting traffic with client
- Essential when using simple authentication; avoid password being sent in clear text over the network
- Here is the simplest use, where there is no requirement to store local copies of the certificates, but the identity of the server is not checked:

```
my $r = $ldap->start_tls( verify => 'none' );
```

- See `perldoc Net::LDAP` and `perldoc Net::LDAP::Security` for details and examples.
